IPHT Saclay, 23 September 2021

Loop models

- Self-avoiding simple curves on 2d lattice (nodes and links)
- Place bonds on some links so as to form set of loops
- Weight x per bond and N per loop
- For $|N| \leq 2$, dense and dilute critical points x_c
- Continuum limit of compactified free bosonic field (Coulomb gas)
[Nienhuis, Di Francesco-Saleur-Zuber, Duplantier, Cardy]

Loop models and $U_qsl(2)$

We all love them!

- Applications (polymers, percolation, Ising spin clusters, ...)
- Links to invariant theory and knot theory (Jones polynomials)
- Connection to non-rational CFTs (Koo–Saleur formulas, 3pt and 4pt functions calculations)

Quantum group symmetry

- Local formulation of loop models = **Theory of $U_qsl(2)$ invariants**
- Local bits of the loop model are $U_qsl(2)$ -invariant operators!
- Temperley–Lieb diagrams and (dilute) Temperley–Lieb algebra

Theory of diagrammatical $U_qsl(\textcolor{red}{n})$ invariants

Math

- Well-known for mathematicians starting from the pioneering work of Kuperberg in 1992-1996
- He's developed a diagrammatic approach to classification of invariants of $U_qsl(3)$ – **spider diagrams** – they classify invariants in $\square \otimes \square \otimes \overline{\square} \otimes \dots$
- Then many people have contributed to generalisations for higher ranks:
 - H. Murakami, T. Ohtsuki and S. Yamada in 1998 (MOY invariants)
 - M.-J. Jeong and D. Kim in 2005
 - H. Wu in 2009
 - S. Cautis, J. Kamnitzer and S. Morrison in 2012

Physics

- The math works are all motivated by low-dimensional topology (knot theory, mfd invariants, etc)
- Theory of $U_qsl(\textcolor{red}{n})$ -type diagrams is largely unknown to physicists

From Loop to Web models

Quantum group symmetry

Elementary/local bits of the model are $U_qsl(\textcolor{red}{n})$ -invariant operators!

Example of $U_qsl(3)$ -type generalisation:

Why are we interested in them?

- Allow for branchings and bifurcations (with weights)
- Domain walls in spin systems
- CFT in the continuum limit with W -algebra chiral symmetry
- Koo-Saleur formula in higher rank?

$U_qsl(3)$ Web model: Lattice configurations

- Hexagonal lattice \mathbb{H} with nodes and links
- Configuration c by drawing bonds on some links, with constraints:
 - Nodes have valence 0, 2 or 3: closed web with 3-valent vertices
 - Each bond is oriented. Orientations conserved at 2-valent nodes
 - Vertices are sources or sinks (all bonds point in or out)
- Each configuration as an abstract graph (keep only vertices and edges) is **closed, planar, trivalent, bipartite**.

$U_qsl(3)$ Web model: **Non-local** weight of a configuration

Reduction rules: **spider relations**

[Kuperberg'96]

$$\text{circle with arrow} = [3]_q = q^2 + 1 + q^{-2}$$

$$\text{vertical line with two loops} = [2]_q \text{ vertical line}$$

$$\text{two vertical lines with horizontal crossings} = \text{two parallel vertical lines} + \text{two arcs}$$

$U_qsl(3)$ Web model: **Non-local** weight of a configuration

Reduction rules: **spider relations**

[Kuperberg'96]

$$\text{circle with arrow} = [3]_q = q^2 + 1 + q^{-2}$$

$$\text{vertical line with a loop} = [2]_q \text{ vertical line}$$

$$\text{crossing of two vertical lines} = \text{two parallel vertical lines} + \text{two arcs}$$

- Rotated and arrow-reversed diagrams
- A web component always has ≥ 1 polygon(s) of degree 0, 2 or 4
- The three rules evaluate any web configuration c to its weight $w_K(c)$

Statistical model

- Local fugacities for bonds and vertices:
 - x_1 (**up** bond) x_2 (**down** bond)
 - y (**sink** vertex) z (**source** vertex)
- Sum over all configurations $c \in K$ on \mathbb{H}
- Partition function:

$$Z_K = \sum_{c \in K} x_1^{N_1} x_2^{N_2} (yz)^{N_V} w_K(c)$$

with N_1 up-bonds, N_2 down-bonds, and N_V vertex pairs

$U_qsl(3)$ Web model: Partition function

Example

- Non-local weight $w_K(c) = [2]_q [3]_q^2$
- Total weight of the configuration on \mathbb{H} is $x_1^{22} x_2^{13} yz [2]_q [3]_q^2$

$U_{qsl}(3)$ Web model: Relation to spin models

\mathbb{Z}_3 -spin model

- Spins $\sigma_i \in \mathbb{Z}_3 = \{0, 1, 2\}$ on nodes i of a triangular lattice $\mathbb{T} = \mathbb{H}^*$
- Interaction along link (ij) of \mathbb{T} defined as $x_{\sigma_j - \sigma_i}$ with j to the right of i

Mapping to the web model

- Set $x_0 = 1$, so this spin model associates a non-trivial weight, x_1 or x_2 , to each piece of domain wall between **unequal** spins, i.e. a link of \mathbb{H} that is dual to link (ij) of \mathbb{T} satisfying $\sigma_i \neq \sigma_j$
- Orient accordingly: the link on \mathbb{H} is up (down) if $\sigma_j - \sigma_i = 1$ ($= 2$)
- Vertices appear at a junction of three spin clusters, and they are either sources or sinks according to how the spins around them are arranged.

Bijection between web configurations and spin configurations modulo the global \mathbb{Z}_3 action

$U_qsl(3)$ Web model: Relation to spin models

$U_qsl(3)$ Web model: Relation to spin models

Partition function

$$Z_{\text{spin}} = 3 \sum_{c \in K} x_1^{N_1} x_2^{N_2}$$

Equivalence condition

- Neither vertex weights nor non-local weights in the spin model
- Equivalent to the web model ($Z_{\text{spin}} = 3Z_K$) if the following relation holds for all configurations:

$$(yz)^{N_V} w_K(c) = 1$$

$U_qsl(3)$ Web model: Relation to spin models

Equivalence at a special point

$$q = e^{i\frac{\pi}{4}}$$
$$yz = 2^{-\frac{1}{2}}$$

Idea of proof: Absorb y and z into the vertices and use $[3]_q = 1$ and $[2]_q = \sqrt{2}$

 = 1

 = 

 = $\frac{1}{2}$   + $\frac{1}{2}$  

Use spiders of Cautis-Kamnitzer-Morrison'12

- Webs are still closed, oriented, planar, trivalent graphs
But not always bipartite as before
- Edges carry an integer flow $i \in \llbracket 1, n-1 \rrbracket$.
 - Flow labels fundamental representations of $U_qsl(n)$
 - Orientation distinguishes between two duals
- Generators conserve flow, or change by n due to tags:

Spider relations:

$$\begin{aligned}
 \text{Circle with arrow } k &= \begin{bmatrix} n \\ k \end{bmatrix}_q \\
 \text{Loop with arrows } k, l &= \begin{bmatrix} k+l \\ k \end{bmatrix}_q \text{ vertical line } k+l \\
 \text{Loop with arrows } k, l &= \begin{bmatrix} n-k \\ l \end{bmatrix}_q \text{ vertical line } k
 \end{aligned}$$

and an associativity rule:

$$\begin{aligned}
 &\text{Tree with root } k+l+m \text{ and children } k+l, m \text{ (left)} \\
 &= \text{Tree with root } k+l+m \text{ and children } k, l+m \text{ (right)}
 \end{aligned}$$

and a square rule:

$$\begin{aligned}
 &\text{Square with arrows } k, l \text{ and internal labels } k-1, l+1 \\
 &= \text{Square with arrows } k, l \text{ and internal labels } k+1, l-1 + [k-l]_q \text{ vertical lines } k, l
 \end{aligned}$$

and the tag rules...

Short summary of results

- Case $n = 3$ gives back Web model based on Kuperberg's spiders
- Case $n = 2$ gives the well-known Nienhuis loop model
- Special point $q = e^{i\pi/(n+1)}$ equivalent to \mathbb{Z}_n spin model

Short summary of results

- Case $n = 3$ gives back Web model based on Kuperberg's spiders
- Case $n = 2$ gives the well-known Nienhuis loop model
- Special point $q = e^{i\pi/(n+1)}$ equivalent to \mathbb{Z}_n spin model

$U_qsl(n)$ Web models: Criticality?

- \mathbb{Z}_n spin models known to be critical
→ $U_qsl(n)$ Web models have the special critical point for any $n \geq 2$
- Web models likely have larger critical manifold varying q and x, y, z

Short summary of results

- Case $n = 3$ gives back Web model based on Kuperberg's spiders
- Case $n = 2$ gives the well-known Nienhuis loop model
- Special point $q = e^{i\pi/(n+1)}$ equivalent to \mathbb{Z}_n spin model

$U_qsl(n)$ Web models: Criticality?

- \mathbb{Z}_n spin models known to be critical
→ $U_qsl(n)$ Web models have the special critical point for any $n \geq 2$
- Web models likely have larger critical manifold varying q and x, y, z

To investigate criticality we need a local formulation

- Analogous to vertex models and $O(N)$ models
- The locality enables us to define a transfer matrix
- Good for numerical study and critical exponents calculation

$U_qsl(3)$ Web models: Local reformulation

Basic idea

- Decorate bonds by extra degrees of freedom ($n = 3$ colours **R****G****B**)
- They allow to redistribute the web weight locally
- Summing over colours gives back the undecorated model
- Each link can now be in 7 different states of $\mathcal{H} = \mathbb{C} \oplus \mathbb{C}^3 \oplus \overline{\mathbb{C}}^3$

Reminder for loop models or $n = 2$ case

- Write the loop fugacity as $q + q^{-1} = [2]_q$
- Orient each loop in two ways (clockwise, anticlockwise)
- a piece carries weight $q^{-\frac{\vartheta}{2\pi}}$ when it bends an angle ϑ

$$= xq^{-\frac{1}{6}}$$

$$= xq^{\frac{1}{6}}$$

$$= 1$$

Reminder for loop models or $n = 2$ case

- Write the loop fugacity as $q + q^{-1} = [2]_q$
- Orient each loop in two ways (clockwise, anticlockwise)
- a piece carries weight $q^{-\frac{\vartheta}{2\pi}}$ when it bends an angle ϑ

$$= xq^{-\frac{1}{6}}$$

$$= xq^{\frac{1}{6}}$$

$$= 1$$

- Better to think of these two “orientation” as colourings
- The analogue for $n = 3$ is the three colours **RGB**
- The orientations distinguish (for $n = 3$) fundamental \mathbb{C}^3 and its dual $\overline{\mathbb{C}}^3$ but for $n = 2$ the two coincide!

$U_qsl(3)$ Web models: Local reformulation

Basic idea for $n = 3$

3 colours **RGB** and each coloured web c is assigned a weight $w_{\text{col}}(c)$:

- Loop weight $[3]_q = q^2 + 1 + q^{-2}$ for sum over clockwise loop

$$= xq^{\frac{1}{3}},$$

$$= x,$$

$$= xq^{-\frac{1}{3}}$$

Here, $x_1 = x_2 = x$ for convenience

- Opposite phases for anticlockwise loops

$U_qsl(3)$ Web models: Local reformulation

Basic idea for $n = 3$

3 colours **RGB** and each coloured web c is assigned a weight $w_{\text{col}}(c)$:

- Loop weight $[3]_q = q^2 + 1 + q^{-2}$ for sum over clockwise loop

$$= xq^{\frac{1}{3}},$$

$$= x,$$

$$= xq^{-\frac{1}{3}}$$

Here, $x_1 = x_2 = x$ for convenience

- Opposite phases for anticlockwise loops
- and more tricky for vertices (sinks/sources):

$$= zx^{\frac{3}{2}}q^{-\frac{1}{6}}$$

$$= zx^{\frac{3}{2}}q^{\frac{1}{6}}$$

- Plus opposite phases for opposite directions

Idea of proof

Digon rule

$$\text{Digon 1} + \text{Digon 2} = q^{\frac{1}{6} \times 2 + \frac{2}{3}} \text{Line} + q^{-\frac{1}{6} \times 2 - \frac{2}{3}} \text{Line} = [2]_q \text{Line}$$

Square rule

$$\text{Square 1} + \text{Square 2} = \text{Crossing} + \text{Loop}$$

Double row transfer matrix T

- Define in terms of elementary blocks – the local transfer matrices

$$t_{(1)} = \begin{array}{c} \diagup \quad \diagdown \\ | \end{array} \quad \text{and} \quad t_{(2)} = \begin{array}{c} \diagup \quad \diagdown \\ | \end{array}$$

$$t_{(1)} : \quad \mathcal{H} \otimes \mathcal{H} \rightarrow \mathcal{H}$$

$$t_{(2)} : \quad \mathcal{H} \rightarrow \mathcal{H} \otimes \mathcal{H}$$

with matrix elements = local weights

- $t = t_{(2)} t_{(1)} : \quad \mathcal{H} \otimes \mathcal{H} \rightarrow \mathcal{H} \otimes \mathcal{H}$

-

$$T = \left(\prod_{k=0}^{L-1} t_{2k+1} \right) \left(\prod_{k=1}^{L-1} t_{2k} \right) \quad \text{so that} \quad Z_K = \langle T^M \rangle$$

Double row transfer matrix

Transfer matrix T is $U_q sl(3)$ intertwiner!

$$\begin{aligned}
 t_{(1)} = & \begin{array}{c} \text{Y-junction with 3 solid lines} \end{array} = z x_1 x_2^{\frac{1}{2}} \begin{array}{c} \text{Y-junction with 1 solid line up, 2 solid lines down-left/down-right} \end{array} \\
 & + y x_1^{\frac{1}{2}} x_2 \begin{array}{c} \text{Y-junction with 1 solid line up, 1 solid line down-left, 1 dashed line down-right} \end{array} + x_1 \begin{array}{c} \text{Y-junction with 1 solid line up, 1 solid line down-left, 1 dashed line down-right} \end{array} \\
 & + x_1 \begin{array}{c} \text{Y-junction with 1 solid line up, 1 dashed line down-left, 1 solid line down-right} \end{array} + x_2 \begin{array}{c} \text{Y-junction with 1 solid line up, 1 dashed line down-left, 1 solid line down-right} \end{array} \\
 & + x_2 \begin{array}{c} \text{Y-junction with 1 solid line up, 1 dashed line down-left, 1 solid line down-right} \end{array} + x_1^{\frac{1}{2}} x_2^{\frac{1}{2}} \begin{array}{c} \text{Y-junction with 1 dashed line up, 2 solid lines down-left/down-right} \end{array} \\
 & + x_1^{\frac{1}{2}} x_2^{\frac{1}{2}} \begin{array}{c} \text{Y-junction with 1 dashed line up, 1 solid line down-left, 1 dashed line down-right} \end{array} + \begin{array}{c} \text{Y-junction with 1 dashed line up, 1 solid line down-left, 1 dashed line down-right} \end{array}
 \end{aligned}$$

and similarly for $t_{(2)}$

Double row transfer matrix

All terms are compositions/juxtapositions of elementary $U_qsl(3)$ -intertwiners:

plus those with reversed arrows.

Example

So ...

Summary for the strip/cylinder geometry

- Elementary blocks of T and T itself are $U_qsl(3)$ -intertwiners and it is very simple to compute them
- We have also construction of T_{cyl} in the periodic case or cylinder geometry
- In the periodic case, again, elementary blocks of T_{cyl} are $U_qsl(3)$ -intertwiners (however T is not)
- We can now diagonalise T_{cyl} numerically and study phase diagrams!

Phase diagram of Web model

Effective central charge c_{eff}

- Free energy density f_L on a cylinder with circumference of L hexagons

$$f_L = -\frac{2}{\sqrt{3}L} \log(\Lambda_{\text{max}})$$

- Calculate c_{eff} using finite-size scaling:

$$f_L = f_{\infty} - \frac{\pi c_{\text{eff}}}{6L^2} + o\left(\frac{1}{L^2}\right)$$

Phase diagram for $q = e^{i\pi/5}$ in the (\sqrt{x}, y) plane

- Dilute phase $c = \frac{6}{5}$ and dense phase $c = \frac{4}{5}$
- At $y = 0$ (horizontal axis) we get $O(N)$ loop model with $N = 2[3]_q$

Summary

- Web models generalise the $U_qsl(2)$ -invariant loop model to $U_qsl(n)$ -invariant models
- Geometrical content with applications to \mathbb{Z}_n spin interfaces
- In $U_qsl(3)$ case, we identified dense and dilute critical points for $q = e^{i\gamma}$ and $\gamma \in (0, \pi)$
- Also, we found precursors of electro-magnetic operators \rightarrow starting point for Coulomb gas calculations and CFT identification

Summary

- Web models generalise the $U_qsl(2)$ -invariant loop model to $U_qsl(n)$ -invariant models
- Geometrical content with applications to \mathbb{Z}_n spin interfaces
- In $U_qsl(3)$ case, we identified dense and dilute critical points for $q = e^{i\gamma}$ and $\gamma \in (0, \pi)$
- Also, we found precursors of electro-magnetic operators \rightarrow starting point for Coulomb gas calculations and CFT identification

What next?

- Coulomb gas description and fractal dimension of defects
- Statistical models for other spiders of types $U_qso(n)$ and $U_qsp(2n)$
- Detailed representation theoretical study, eg standard modules
- Link to integrable models?
- SLE-like description of **branching** curves?

Happy Birthday, Hubert!
